

Exploiting Big Data in Engineering Adaptive Cloud Services

Patrick Martin

Database Systems Laboratory

School of Computing, Queen's University

Big Data

- 3 v's: *Volume, Velocity, Variety*
- *Data analytics* to support effective on-line decision making

Adaptive Cloud Services

- Software services offered from *private/public/multi/hybrid* clouds
- Exploit ***elasticity*** of clouds
- Exploit ***mobility*** across cloud providers

Claim

Big data has an important role to play in the engineering of adaptive software systems, in general, and adaptive cloud services, in particular.

Why QoS-Aware Management?

- Consumer – provider relationship in clouds will rely on SLAs
- Providers will need to support differentiated QoS
- QoS involves application-level metrics that are understood by both parties
- QoS determines resource requirements

Challenges in QoS-Aware Management

- *Complexity* of applications and of cloud environments
- *Varying demands* from an application
- *Heterogeneity* of cloud offerings
- *Varying service quality* from a cloud provider
- *Conflicting goals* of application and cloud provider

Role of Big Data

Role of Big Data

Brokering - CBR

- Big data used to construct case base for cloud provider selection
 - Case features based on resource demands
 - Demands extracted by analyzing performance logs of services in current configurations
- CBR used to find potential matching deployments that can be adapted to new service's requirements

Monitoring

- Big data collected and analyzed during service execution
 - Multiple streams of data
 - ETL, aggregation over time and/or sources
 - Triggers decision-making
 - Used to adapt workload and performance models

Workload Forecasting

- Big data used to
 - Classify requests
 - Characterize resource demands of classes
 - Identify trends in request intensities (time series analysis)
- Models need to adapt to changes in workload

Performance Prediction

- Big data used to build statistical models of performance
 - Clouds increase the number of parameters and the variability in the modeling process
 - Interactions among workload requests must be accounted for in the models
- Models need to adapt to changes in workload and configuration
 - Parameter selection for models
 - Ensemble models

Summary

- Big data plays important role in engineering adaptive cloud services
 - Brokering, provisioning, monitoring, workload forecasting and performance prediction

The big challenge  *Efficient online adaptation of the models!*

Runtime Model Management

- Adaptive software systems use a LOT of models
- Adaptation middleware needs to provide model management
 - Store and describe models (metrics, policies, relationships)
 - Efficient maintenance of models at runtime to minimize impact on managed system

Thank you
