## Expressions and Statements

- › Expression = returns a value and produces no side effect
  - › (1+2)
- › Statement = doesn't return a value but is executed for it's sideeffects
  - › print(5)
- › In many languages the distinction is blurry
- › Similar to functions vs procedures

2

## Evaluation of expressions

- › For “pure” expressions order of evaluation of subexpressions doesn't matter
- › For side-effects of course it matters
- › Sequence operator in C
  - › x = 1; y = 2;
  - › x = (y+=1, x+=y, x+1) /\* value of rightmost expression returned \*/
  - › After x = 5, y = 3

3

CS330 Spring 2003

## Control

- › GOTO
- › If-statements
  - › Dangling else
    - › if (e1) if (e2) S1 else S2
    - › most closely nested rule
  - › Solution: bracketing keyword
    - › Ada – if “brackets” with end if
    - › Algol68 – if “brackets” with fi

## Switch statement in C

```
switch (x-1)
{
  case 0: y=0;
          z=2;
          break;
  case 2:
  case 3:
  case 4:
          y=3;
          z =1;
          break;
  default:
          break;
}
```

Switch statement “falls through”  
be careful about forgetting break  
statements

5

## Loops

while (e) S;

Syntactic sugar:

do S while (e);

=

S;

while (e) S;

break : exit loop immediately  
continue: skip remainder of loop and  
start again

All computer games:

```
while(1)
{
  if (...) break;
}
```

## Exception Handling

- › Exception raised or thrown
- › Exception handler “handles” or “catches” an exception
- › Initial motivation: handling graceful hardware interrupts/problems
- › Motivation today: libraries can detect errors but in many cases the handling needs to be done by the user

7

## Exceptions

- › Languages with exceptions
  - › C++, Java, Ada, ML, CLISP
- › Languages without exceptions
  - › C, Scheme, Smalltalk

8

CS330 Spring 2003

## Propagating the exception

- > Call unwinding (try to find handler in closest block (subexpression) propagate upwards)
- > Where to continue execution ?
  - > resumption model
  - > termination model (easier to implement and has better semantics, resumption can be simulated)
- > Significant run-time overhead
  - > typically no cost when no exception

## Procedures and environments

- > functions vs procedures similar to expressions vs statements
- > Initially as a way to split compilation
- > Fortran: static entity without recursion
- > Algol60, C: recursion
- > LISP and functional languages: functions are first class citizens

10

## Procedure definition and activation

```
// C++ code
void intswap(int&, int&); // specification

void intswap(int& x, int& y) // specification
{
    int t = x; // body
    x = y;     // body
    y = t;     // body
}

intswap(a,b); // activation
```

callee  
caller  
formal parameters  
actual parameters

11

## Procedure Semantics

- > Activation record = memory allocated for one activation of a procedure
- > Communication with the outside world through arguments and non-local references

12

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## An example in C

```
int x;
void B(void)
{ int i;
  i = x / 2;
  ... }

void A(void)
{ int x,y;
  ...
  x = y * 10;
  B();
}

main() { A(); }
```

|   |
|---|
| x |
| x |
| y |
| i |

Global environment (defining environment of B)

Activation record of A (calling environment of B)

## A possibility ?

- › Do everything with argument passing
  - › works ok for variables
  - › what about constants and functions ?
- › Closed form
  - › strive for it
- › Closure = code of a function together with a representation of the defining environment (used to resolve all outstanding nonlocal references)

## Parameter Passing Mechanisms

- › Pass-by-value
- › Pass by reference
- › Pass by value-result
- › Pass by Name (delayed evaluation)

15

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## Pass-by-value

Replace all parameters with their values  
(however values can be changed using pointers)

```
void init_p (int *p) // the value is the pointer
{ *p = 0; }
int init_ptr(int *p)
{ p = (int *) malloc(sizeof(int)); } // will be ignored
```

Java:  
void append\_1(Vector v) // works  
{ v.addElement(new Integer(1)); }

```
void make_new (Vector v)
{ v = new Vector(); } // will be ignored
```

16

CS330 Spring 2003

## Pass by reference

- > Parameter becomes an alias for the argument – changes are reflected outside (default in Fortran)

```
void inc(int& x) // C++
{ x++; }
```

```
// C simulation
void inc(int *x)
{ (*x)++; }
```

```
procedure inc(var x: integer); // Pascal
begin
  x := x + 1;
end;
```

17

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## Pass by value result

- > Similar to pass-by-reference but no aliasing (copy-in, copy-out)

```
void p(int x, int y)
{
  x++;
  y++;
}
```

```
pseudo-C notation real C has
only pass-by-value

pass-by-reference result = 3
pass-by-value-result = 2
```

```
main()
{ int a = 1;
  p(a,a);
}
```

18

## Pass-by name and Delayed evaluation

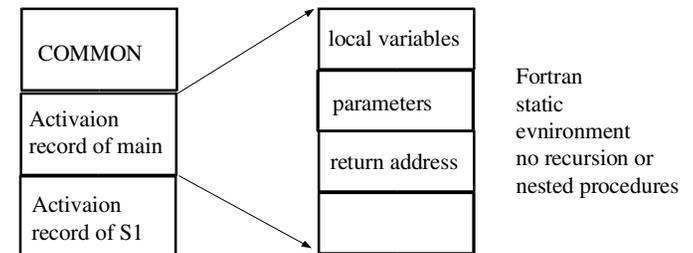

Argument is not evaluated until it's actual use in the called procedure - the "name" textual representation at the point of call, replace the name of the parameter.

Weird semantics in the presence of side effects  
Works nicely in Haskell which is a pure functional language

## Procedure Environments, Activations and Allocation

20

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## Stack-Based Runtime

21

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## Nested procedures

- > C and Fortran no nested procedures
  - > all non-local references global (easy to find)
- > Nested procedures (Pascal, Ada, Modula-2)
- > Following the control links results in dynamic scoping rather than lexical
- > Additional field called access link: link to lexical or defining environment
- > closure <ep, ip>

22

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## Maximum flexibility

- > Procedures are first class values: they can be created at will
- > Stack-based environment impossible
- > Basically have to store full environment and code (closure) for everything (ML, Scheme, LISP)
- > Automatic reclamation of storage
  - > Reference counting
  - > Garbage collection

23

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## Dynamic Memory Management

- > Never deallocate
  - > Large memory requirement
- > Maintaining free space
  - > list of free blocks – coalescing, fragmentation (done with disk drives too)
- > Reference counting (eager)
- > Mark and sweep
- > Generational garbage collection

24

CS330 Spring 2003  
Copyright George Tzanetakis, University of Victoria

## Mark and sweep

- › Lazy: Allocator runs out of space
- › First pass: Follow all pointers recursively and mark everything reachable (extra bit)
- › Second pass: Move all unreferenced cells back to free list
- › Problem: processing delays

## Generational garbage collection

- › Spread cost more evenly
- › Allocated objects that survive long enough are simply copied to permanent space and never get reallocated
- › Only newer storage allocations need to be searched
